

# How to format disk in Linux

14 December 2022 by Korbin Brown

Formatting a disk will get it ready for use as a storage device on your [Linux system](#). The process involves [partitioning the disk](#), adding a file system to the partition (this is the “formatting” part), and then mounting the partition to some path where you plan to access it from. This might sound complex or like a lot of steps, but it really only takes a few minutes.

This process will wipe all the data from your hard disk and get it ready for use under Linux or another system. In this tutorial, we will cover the step by step instructions to format a hard drive or solid state drive on a Linux system. We will show the steps for both command line and GUI methods, so you can follow along with set of instructions you are most comfortable with. Let’s get started.

## In this tutorial you will learn:

- How to format a disk drive in Linux via GUI
- How to format a disk drive in Linux via command line

How to format disk in Linux

*Software Requirements and Linux Command Line Conventions*

Category	Requirements, Conventions or Software Version Used
System	Any <a href="#">Linux distro</a>
Software	gdisk, gparted
Other	Privileged access to your Linux system as root or via the <a href="#">sudo</a> command.
Conventions	<b>#</b> – requires given <a href="#">linux commands</a> to be executed with root privileges either directly as a root user or by use of <a href="#">sudo</a> command <b>\$</b> – requires given <a href="#">linux commands</a> to be executed as a regular non-privileged user

## How to format a disk on Linux via command line

[!\[\]\(de95854c7ee024cfadc48187bbb781b2\_img.jpg\) Follow LinuxConfig.org on Twitter for the latest tips and tricks about Linux!](#)

## DID YOU KNOW?

If your intention is to use the hard drive as a primary disk for a Linux installation, then no partitioning is required as any decent Linux operating system will do the job for you during the installation process.

Open a terminal and type the following commands to format your hard disk drive. Here we will be using the **gdisk** command line tool, which should already be installed by default on all major **Linux distros**.

**Step 1** First, let's figure out how to identify the disk drive we wish to format. The name should start with **/dev/sd** and then a letter. Type the following command in terminal to see:

```
$ sudo fdisk -l
```

```

Disk /dev/sda: 50 GiB, 53687091200 bytes, 104857600 sectors
Disk model: VMware Virtual S
Units: sectors of 1 * 512 = 512 bytes
Sector size (logical/physical): 512 bytes / 512 bytes
I/O size (minimum/optimal): 512 bytes / 512 bytes
Disklabel type: gpt
Disk identifier: 0E2C47C0-227D-4DE6-8EF6-97D947E23C41

Device            Start       End   Sectors   Size Type
/dev/sda1         2048        4095     2048    1M BIOS boot
/dev/sda2         4096    1054719   1050624   513M EFI System
/dev/sda3       1054720 104855551 103800832 49.5G Linux filesystem

Disk /dev/sdb: 2.93 TiB, 3221225472000 bytes, 6291456000 sectors
Disk model: VMware Virtual S
Units: sectors of 1 * 512 = 512 bytes
Sector size (logical/physical): 512 bytes / 512 bytes
I/O size (minimum/optimal): 512 bytes / 512 bytes

Disk /dev/loop9: 45.93 MiB, 48160768 bytes, 94064 sectors
Units: sectors of 1 * 512 = 512 bytes
Sector size (logical/physical): 512 bytes / 512 bytes
I/O size (minimum/optimal): 512 bytes / 512 bytes

Disk /dev/loop10: 346.33 MiB, 363151360 bytes, 709280 sectors
Units: sectors of 1 * 512 = 512 bytes
Sector size (logical/physical): 512 bytes / 512 bytes
I/O size (minimum/optimal): 512 bytes / 512 bytes
  
```

Find your device name in the fdisk output

**Step 2** In our example, the disk drive has been assigned the **/dev/sdb** device path. To create a new partition on the empty disk, we will provide it as an argument to **gdisk**:

```
$ sudo gdisk /dev/sdX
```

**Step 3** The gdisk utility awaits our commands. We would like to create a new partition, so we press “**n**”.

```
Command (? for help): n
```

**Step 4** This will be the first partition that we are creating on this disk, so the answer to the next question is “1”.

```
Partition number (1-128, default 1): 1
```

**Step 5** The next questions are about first and last sector, which will determine the actual size of the partition. In our example we are creating a single partition that will cover the disk, and default values are first partition, first available sector to start, and last sector to end with, which is just what we need. So we will accept the defaults for these questions by simply pressing the **Enter** key.

```
First sector (34-6291455966, default = 2048) or {+-}size{KMGT}:  
Last sector (2048-6291455966, default = 6291455966) or {+-}size{KMGT}:
```

**Step 6** The next questions asks us what kind of file system this partition will be for. We need to enter a hex code that corresponds to our selection. However, the default response is ‘Linux filesystem’ which is exactly what we need. We will once again press the **Enter** key to accept this default value.

```
Current type is 8300 (Linux filesystem)
Hex code or GUID (L to show codes, Enter = 8300):
Changed type of partition to 'Linux filesystem'
```

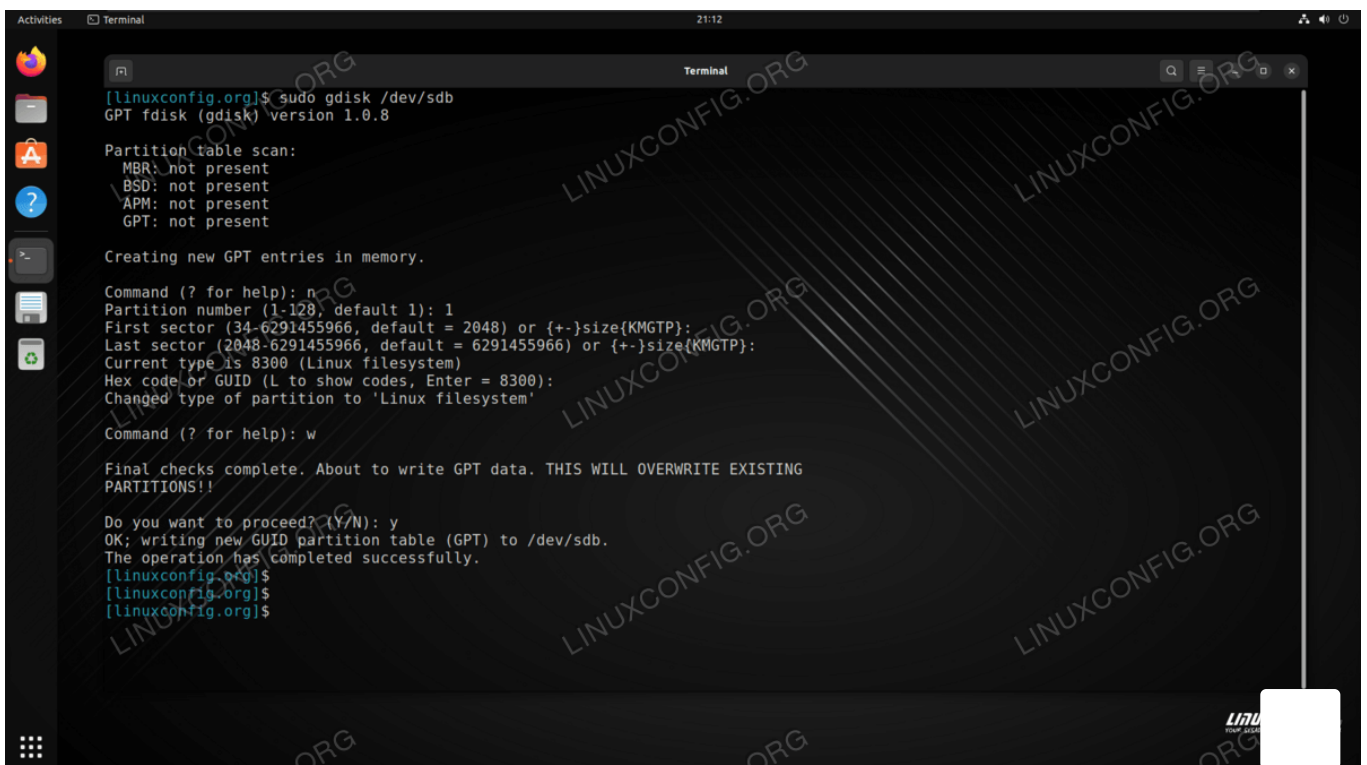

**Step 7** The partition is now complete, but as the utility points out on start, the changes are in-memory only until we write them out to the disk. This is on purpose and the warning is in place for a good reason: by writing out the changes to the disk, we destroy anything that resided on the sector range we cover with our new partition. We are sure there will be no data loss, so we write the changes to disk with the **w** command:

```
Command (? for help): w

Final checks complete. About to write GPT data. THIS WILL OVERWRITE EXISTING
PARTITIONS!!

Do you want to proceed? (Y/N): y
OK; writing new GUID partition table (GPT) to /dev/sdb.
The operation has completed successfully.
```

You will also need to reply **y** to the confirmation prompt to verify that you indeed want to write these changes to the disk, and overwrite existing data.

```
Activities Terminal 21:12
[linuxconfig.org]$ sudo gdisk /dev/sdb
GPT fdisk (gdisk) version 1.0.8

Partition table scan:
  MBR: not present
  BSD: not present
  APM: not present
  GPT: not present

Creating new GPT entries in memory.

Command (? for help): n
Partition number (1-128, default 1): 1
First sector (34-6291455966, default = 2048) or {+}size(KMGTP):
Last sector (2048-6291455966, default = 6291455966) or {+}size(KMGTP):
Current type is 8300 (Linux filesystem)
Hex code or GUID (L to show codes, Enter = 8300):
Changed type of partition to 'Linux filesystem'

Command (? for help): w

Final checks complete. About to write GPT data. THIS WILL OVERWRITE EXISTING
PARTITIONS!!

Do you want to proceed? (Y/N): y
OK; writing new GUID partition table (GPT) to /dev/sdb.
The operation has completed successfully.
[linuxconfig.org]$
[linuxconfig.org]$
[linuxconfig.org]$
```

We are finished partitioning the disk drive with the gdisk utility

**Step 8** Since our block device is `/dev/sdb`, and we just created partition number `1` on the disk, that means our new partition is accessible under the path `/dev/sdb1`. Next, we still need to add a file system to our hard disk. Use the `mkfs` command to format the disk with any file system you would like. In this example, we are using `ext4`, which is the recommended file system for new HDDs and SSDs on Linux:

```
$ sudo mkfs -t ext4 /dev/sdX1
```

**Step 9** We will now use the `mount` command to mount the newly formatted partition on our system. We will mount our disk drive to the `/media/disk` directory.

```
$ sudo mkdir -p /media/disk  
$ sudo mount /dev/sdb1 /media/disk
```

That is all there is to it. You can now access your newly formatted drive under the `/media/disk` directory or where ever you decided to mount it. To make the drive get mounted automatically, see our guide on [configuring the /etc/fstab file](#).

## How to format a disk on Linux via GUI

There are many GUI programs which can also be used to format a hard disk on Linux. In this tutorial, we will focus on using `gparted`, which may or may not already be installed by default on your system.

You can use the appropriate command below to install `gparted` with your system's package manager.

To install `gparted` on [Ubuntu](#), [Debian](#), and [Linux Mint](#):

```
$ sudo apt install gparted
```

To install gparted on [Fedora](#), [CentOS](#), [AlmaLinux](#), and [Red Hat](#):

```
$ sudo dnf install gparted
```

To install gparted on [Arch Linux](#) and [Manjaro](#):

```
$ sudo pacman -S gparted
```

After it is installed, follow the steps below to use gparted to format a disk on Linux:

**Step 1** Get started by searching for the gparted application in your desktop environment's app launcher. You will be prompted for the root password upon opening the program.

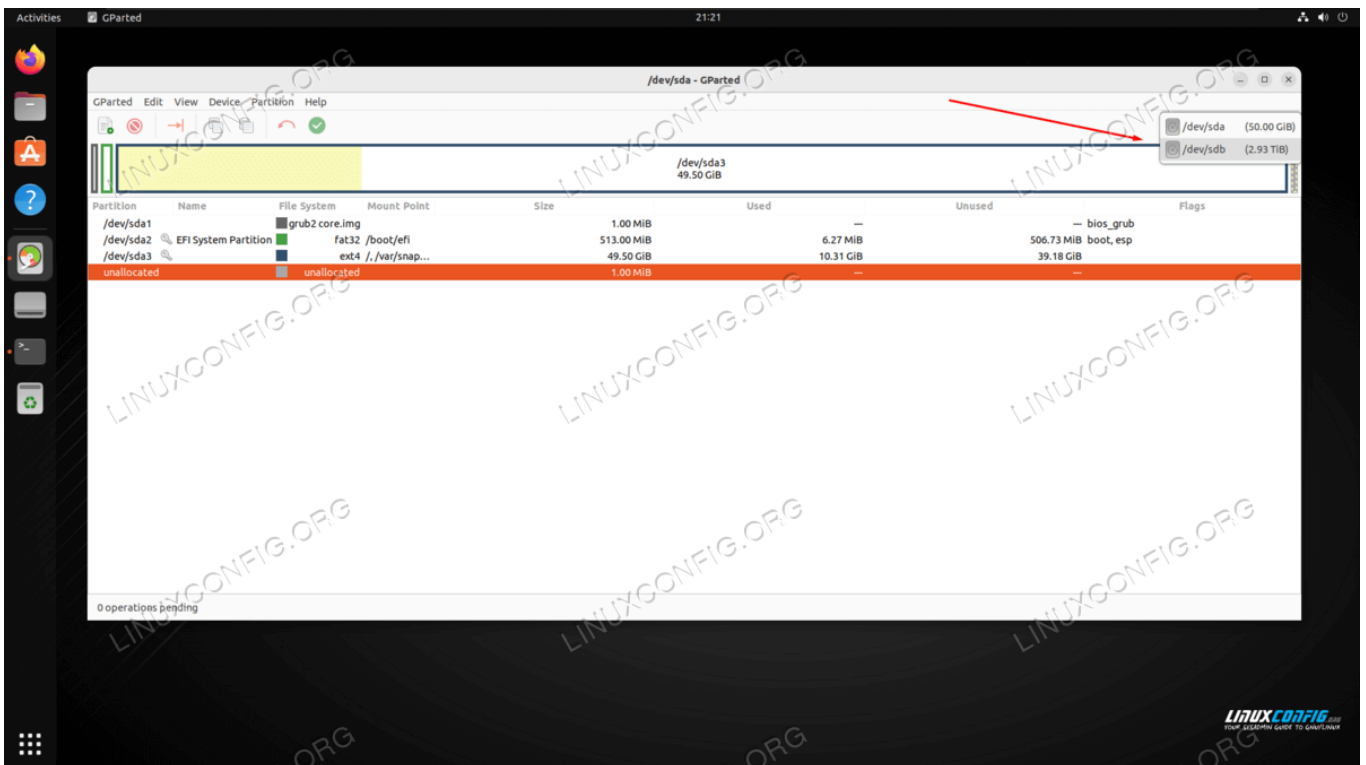

Search for and open the gparted app

You must supply your root password in order to use gparted

**Step 2** The first thing we need to do is select the correct device that we will be working with from the upper right corner. On our test system, this would be `/dev/sdb` as indicated in the screenshot below.

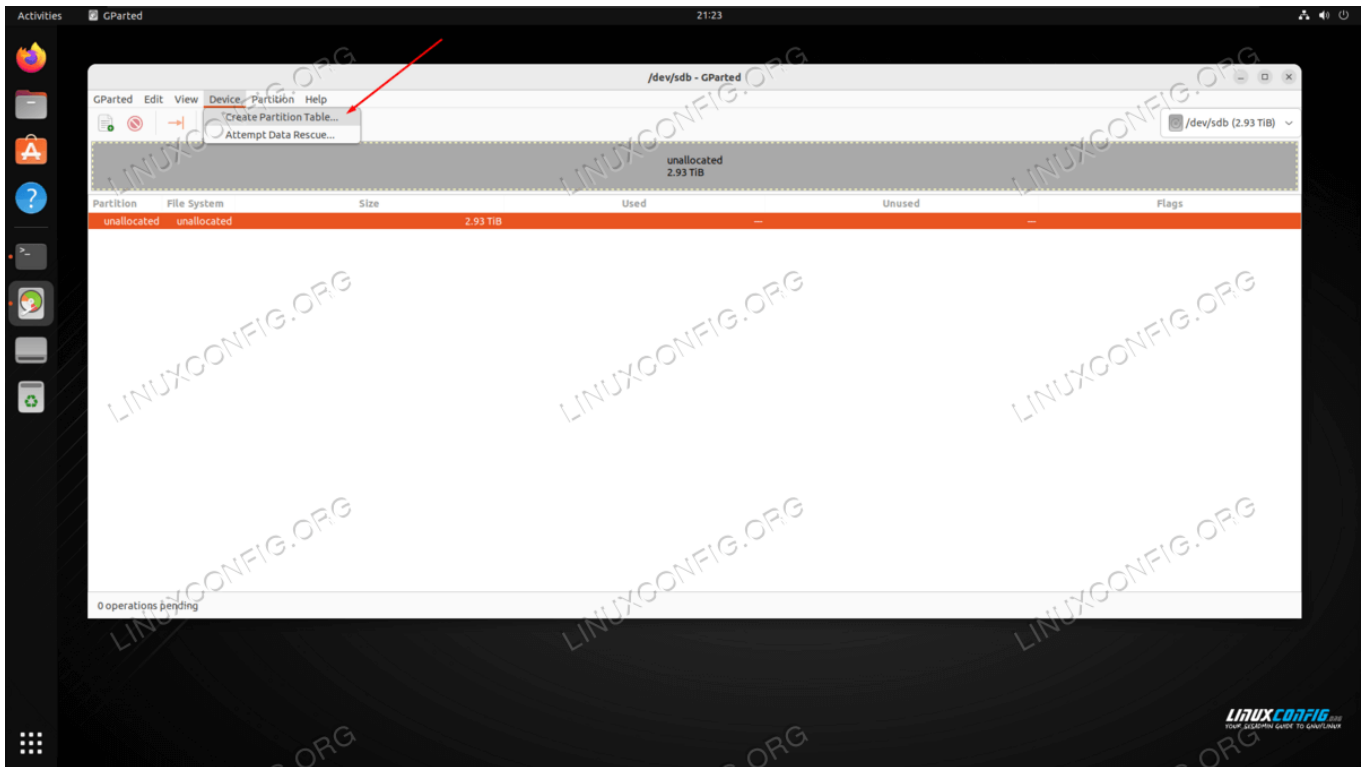

First select the correct hard disk to work with in gparted

 Follow [LinuxConfig.org](https://linuxconfig.org) on Twitter for the latest tips and tricks about Linux!

**Step 3** As you can see, your disk currently has no partitions. Let's add one by going to Device > Create Partition Table.

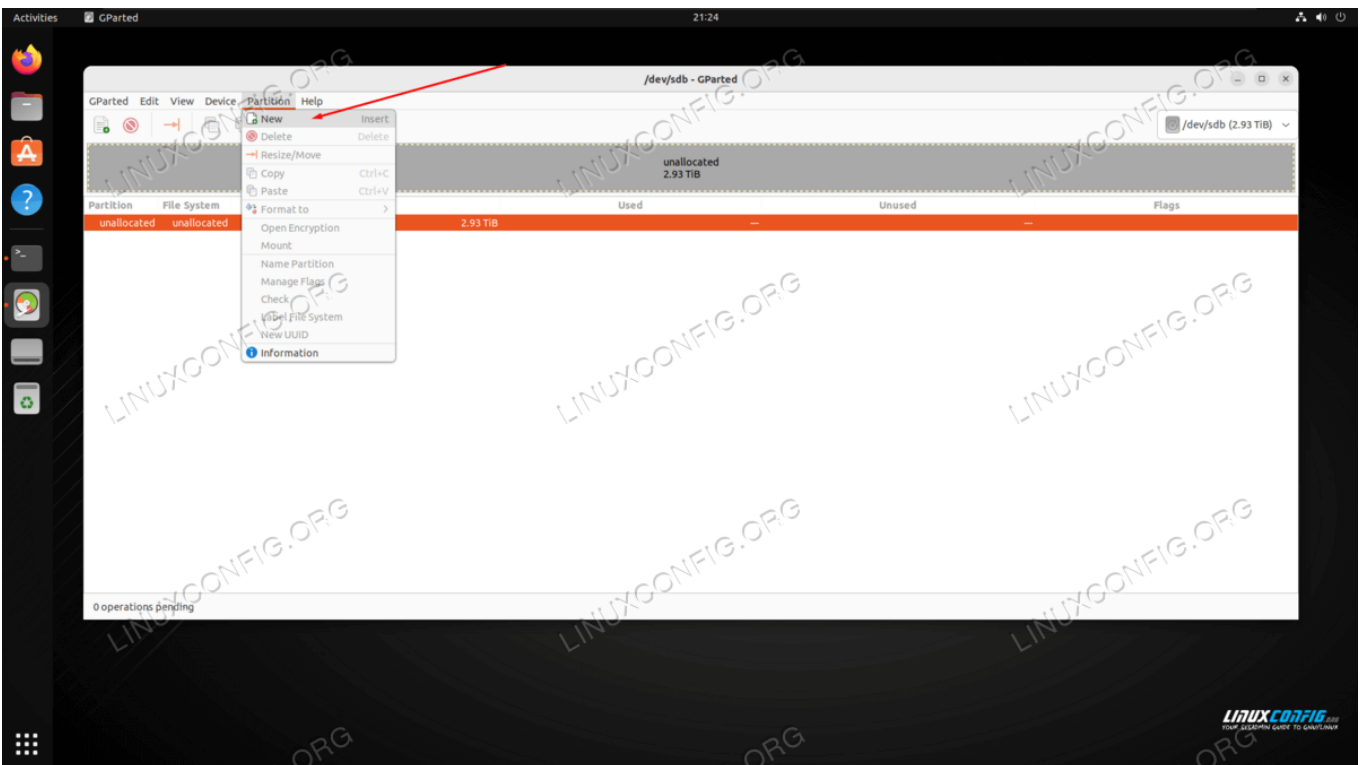

Select to create a new partition table from the Device menu

**Step 4** Next, select the type of partition you would like to create. We will be sticking with **gpt** in our tutorial but feel free to pick something else. GPT is recommended for hard disks greater than 2 TB in size.

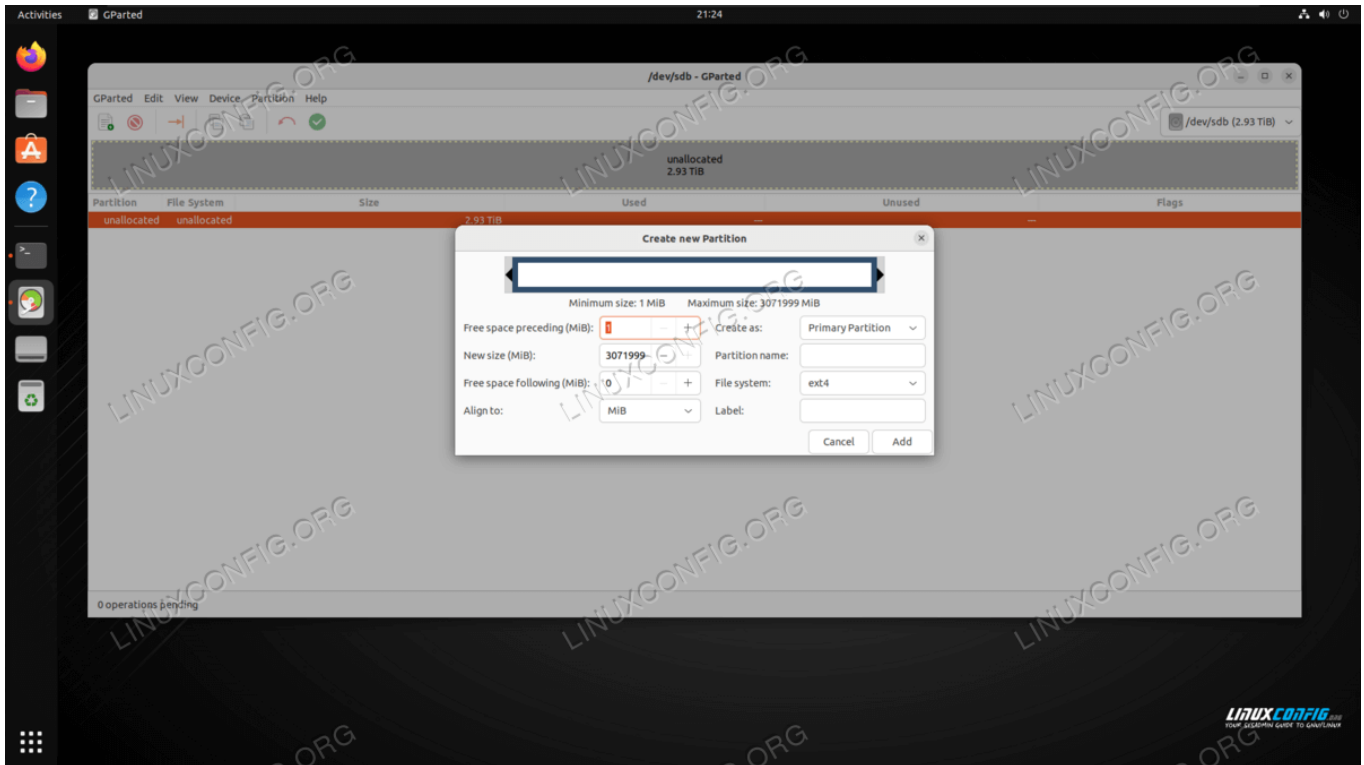

Select partition type and confirm that these changes will erase current disk data

**Step 5** Now that the partition table has been created, we can move forward with adding a new partition to the hard disk. This option can be found by heading to Partition > New.

Select to create a new partition

**Step 6** On this menu, we get to select the size of our new partition. Rather than working with exact values, feel free to use the sliders with your mouse in order to configure the size that you want. For our example, we will simply make one partition that spans the entire size of the hard disk. Click 'Add' when ready to proceed.

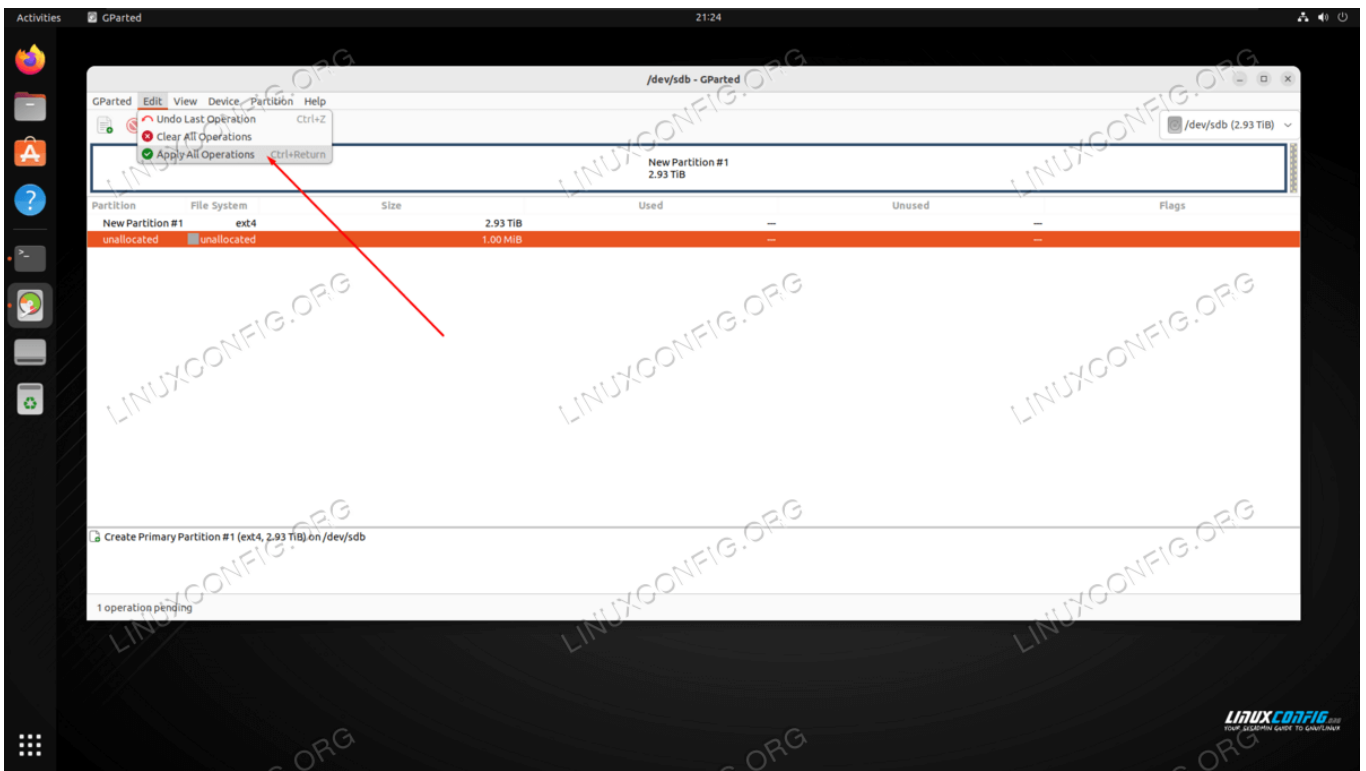

Select size of partition and optionally a name

### NOTE

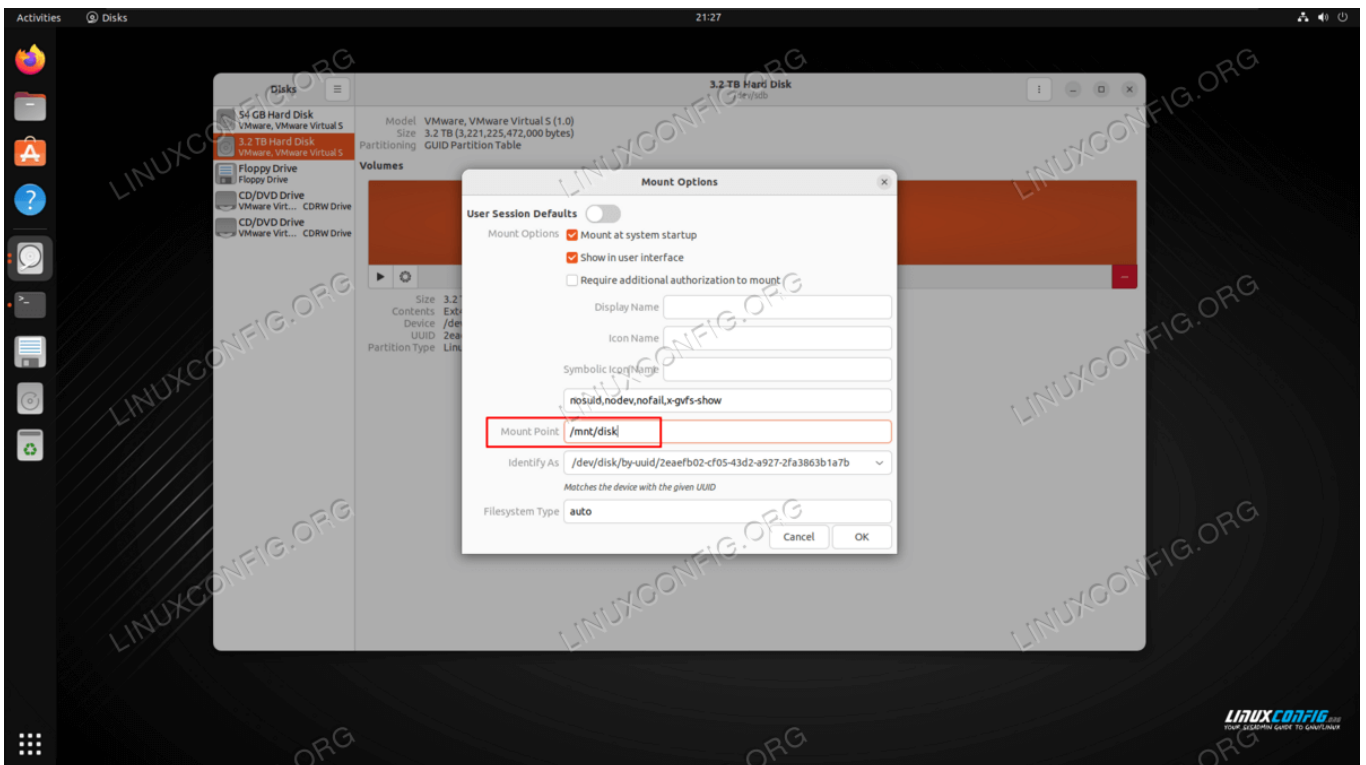

**ext4** is the recommended file system to use on Linux systems, unless you have a special reason to format the disk with some other kind.

**Step 7** The changes are not yet written to the disk, but we can see in the preview pane the configurations that we are about to apply. Once you are ready, click on Edit > Apply All Operations.

Applying the changes to disk

**Step 8** Afterwards, you can open your system's GUI Disks application, select the partition we created earlier, and then mount the partition. Be sure to choose a path where you would like the partition to be accessible from.

Mounting the partition via Disks GUI application

## Closing Thoughts

In this tutorial, we saw how to partition a hard drive from command line and GUI on a Linux system. Managing partitions is a dangerous task that should be performed with the utmost caution. The command line and GUI both prove as viable methods for managing partitions, especially in the case of **parted** and **gparted**, which are closely related tools.
